

CARDAMOM DALEC Model ID 813

January 12, 2021

1 Mathematical Dynamics

Let $\vec{C}^{(t)} = [C_{\text{lab}}^{(t)}, C_{\text{fol}}^{(t)}, C_{\text{roo}}^{(t)}, C_{\text{woo}}^{(t)}, C_{\text{lit}}^{(t)}, C_{\text{som}}^{(t)}]$ denote the labile (lab), foliar (fol), fine root (roo), wood (woo), litter (lit), and soil organic matter (SOM) carbon pools on day t . The dynamics are given by

$$\begin{aligned}\vec{C}^{(t+1)} &= \text{DALEC}_{813}(\vec{C}^{(t)}) \\ &= \text{DALEC}_{813}^{\text{fire}}(\text{DALEC}_{813}^{\text{pre-fire}}(\vec{C}^{(t)})),\end{aligned}$$

where $\text{DALEC}_{813}^{\text{pre-fire}}(\cdot)$ denotes Carbon dynamics in the absence of fire and $\text{DALEC}_{813}^{\text{fire}}(\cdot)$ denotes Carbon Carbon dynamics due to fires.

1.1 Pre-fire Dynamics

Denote $[C_{\text{lab}}^{(t+1)'}, C_{\text{fol}}^{(t+1)'}, C_{\text{roo}}^{(t+1)'}, C_{\text{woo}}^{(t+1)'}, C_{\text{lit}}^{(t+1)'}, C_{\text{som}}^{(t+1)'}] = \vec{C}^{(t+1)'} = \text{DALEC}_{813}^{\text{pre-fire}}(\vec{C}^{(t)})$. The pre-fire dynamics are given by

$$C_{\text{lab}}^{(t+1)'} = f_{\text{lab}} F_{\text{gpp}}^{(t)} + (1 - \phi_{\text{onset}}^{(t)}) C_{\text{lab}}^{(t)}, \quad (1)$$

$$C_{\text{fol}}^{(t+1)'} = \phi_{\text{onset}}^{(t)} C_{\text{lab}}^{(t)} + (1 - \phi_{\text{fall}}^{(t)}) C_{\text{fol}}^{(t)} + f_{\text{fol}} F_{\text{gpp}}^{(t)}, \quad (2)$$

$$C_{\text{roo}}^{(t+1)'} = (1 - \theta_{\text{roo}}) C_{\text{roo}}^{(t)} + f_{\text{roo}} F_{\text{gpp}}^{(t)}, \quad (3)$$

$$C_{\text{woo}}^{(t+1)'} = (1 - \theta_{\text{woo}}) C_{\text{woo}}^{(t)} + f_{\text{woo}} F_{\text{gpp}}^{(t)}, \quad (4)$$

$$C_{\text{lit}}^{(t+1)'} = (1 - (\theta_{\text{lit}} + \theta_{\text{min}}) \rho^{(t)}) C_{\text{lit}}^{(t)} + \phi_{\text{fall}}^{(t)} C_{\text{fol}}^{(t)} + \theta_{\text{roo}} C_{\text{roo}}^{(t)}, \quad (5)$$

$$C_{\text{som}}^{(t+1)'} = (1 - \theta_{\text{som}} \rho^{(t)}) C_{\text{som}}^{(t)} + \theta_{\text{woo}} C_{\text{woo}}^{(t)} + \theta_{\text{min}} \rho^{(t)} C_{\text{lit}}^{(t)}. \quad (6)$$

Here $F_{\text{gpp}}^{(t)}$ denotes the gross primary production (GPP) of Carbon on day t and is a function of meteorology and atmospheric vapor pressure:

$$F_{\text{gpp}}^{(t)} = F_{\text{gpp(max)}}^{(t)} \times \min\left(1, \frac{W^{(t)}}{\omega}\right), \quad (7)$$

where ω is the water stress threshold, $F_{\text{gpp(max)}}^{(t)}$ denotes the maximum GPP on day t , which is given by the Aggregated Canopy Model (ACM), described in [another document](#), and $W^{(t)}$ is the plant-available water pool on day t . $W^{(t)}$ is given dynamically:

$$W^{(t+1)} = W^{(t)} + P^{(t)} - R^{(t)} - ET^{(t)}, \quad (8)$$

where $P^{(t)}$, $R^{(t)}$, and $ET^{(t)}$ are the precipitation, runoff, and evapotranspiration on day t , respectively. Evapotranspiration and runoff are given by

$$ET^{(t)} = F_{\text{gpp}}^{(t)} \frac{VPD^{(t)}}{v_e}, \quad (9)$$

$$R^{(t)} = \begin{cases} \alpha (W^{(t)})^2 & \text{if } W^{(t)} \leq \frac{1}{2\alpha}, \\ W^{(t)} - \frac{1}{2\alpha} & \text{if } W^{(t)} > \frac{1}{2\alpha}, \end{cases} \quad (10)$$

where v_e is the inherent water-use efficiency, α is a runoff decay constant, and $VPD^{(t)}$ is the vapor pressure deficit on day t .

θ_{roo} and θ_{woo} are the fine root and stem C turnover rates, respectively. $\theta_{\text{lit}}\rho^{(t)}$ and $\theta_{\text{som}}\rho^{(t)}$ are the litter and SOM C turnover rates, respectively, and $\theta_{\text{min}}\rho^{(t)}$ is the rate of litter mineralization to SOM, where $\rho^{(t)}$ is a function of daily and monthly average temperature and precipitation values:

$$\rho^{(t)} = e^{\Theta(T^{(t)} - \bar{T})} \left(\left(\frac{P^{(t)}}{\bar{P}} - 1 \right) s_p + 1 \right) \quad (11)$$

Here Θ and s_p are heterotrophic temperature and precipitation dependence factors, \bar{T} and \bar{P} are long term running averages of temperature and precipitation, and $T^{(t)}$ and $P^{(t)}$ are the average temperature and precipitation on day t .

A constant proportion f_{auto} of GPP is lost due to autotrophic respiration. f_{lab} , f_{fol} , f_{roo} , and f_{woo} are constant proportions of GPP allocated to the labile, foliar, fine root, and wood Carbon pools. The sum of these proportions is equal to 1: $f_{\text{lab}} + f_{\text{fol}} + f_{\text{roo}} + f_{\text{woo}} + f_{\text{auto}} = 1$.

$\phi_{\text{onset}}^{(t)}$ and $\phi_{\text{fall}}^{(t)}$ are phenological functions describing the rates of labile to foliar and foliar to litter pool transfer on day t :

$$\phi_{\text{onset}}^{(t)} = \frac{\sqrt{2}}{\sqrt{\pi}} \times \left(\frac{-\log(1 - c_{\text{lr}})}{c_{\text{ronset}}} \right) \times \exp \left[- \left(\frac{s\sqrt{2}}{c_{\text{ronset}}} \sin \left(\frac{t - d_{\text{onset}} - 0.6245c_{\text{ronset}}}{s} \right) \right)^2 \right], \quad (12)$$

$$\phi_{\text{fall}}^{(t)} = \frac{\sqrt{2}}{\sqrt{\pi}} \times \left(\frac{-\log(1 - c_{\text{ll}})}{c_{\text{rfall}}} \right) \times \exp \left[- \left(\frac{s\sqrt{2}}{c_{\text{rfall}}} \sin \left(\frac{t - d_{\text{fall}} - \psi_f}{s} \right) \right)^2 \right]. \quad (13)$$

Here c_{ronset} and c_{rfall} are the labile release and leaf fall periods, d_{onset} and d_{fall} are the leaf onset and fall days, c_{lr} and c_{ll} are the annual labile C release and leaf loss fractions, respectively, and $s = \frac{365.25}{\pi}$.

1.2 Fire Dynamics

Denote $[C_{\text{lab}}^{(t+1)}, C_{\text{fol}}^{(t+1)}, C_{\text{roo}}^{(t+1)}, C_{\text{woo}}^{(t+1)}, C_{\text{lit}}^{(t+1)}, C_{\text{som}}^{(t+1)}] = \vec{C}^{(t+1)} = \text{DALEC}_{813}^{\text{fire}}(\vec{C}^{(t+1)'})$. The fire dynamics are given by

$$C_i^{(t+1)} = C_i^{(t+1)'} - FE_i^{(t)} - FM_i^{(t)}, \quad (14)$$

for $i = \text{lab}, \text{fol}, \text{roo}, \text{woo}$, and

$$C_{\text{lit}}^{(t+1)} = C_{\text{lit}}^{(t+1)'} - FE_{\text{lit}}^{(t)} + FM_{\text{lab}}^{(t)} + FM_{\text{fol}}^{(t)} + FM_{\text{roo}}^{(t)}, \quad (15)$$

$$C_{\text{som}}^{(t+1)} = C_{\text{som}}^{(t+1)'} - FM_{\text{som}}^{(t)} + FM_{\text{woo}}^{(t)}. \quad (16)$$

Here $FE_i^{(t)}$ and $FM_i^{(t)}$ are fire emission and fire mortality fluxes for pool i on day t :

$$FE_i^{(t)} = C_i^{(t+1)'} BA^{(t)} k_i, \quad (17)$$

$$FM_i^{(t)} = C_i^{(t+1)'} BA^{(t)} (1 - k_i) r, \quad (18)$$

where $BA^{(t)}$ is the burned area on day t , k_i are the combustion factors for pool i , and r is the resilience factor.

1.3 Leaf Area Index

Leaf Area Index (LAI) on day t is proportional to the foliar pool on day t :

$$\text{LAI}^{(t)} = \frac{C_{\text{fol}}^{(t)}}{c_{\text{lma}}}, \quad (19)$$

where c_{lma} is the leaf Carbon mass per unit area (sq. m).

2 Comparison to DALEC_813.c

2.1 Dynamic State Variables

$\text{POOLS}[\text{p}+0] = C_{\text{lab}}^{(t)}$	Eqn. (1) = Line 206
$\text{POOLS}[\text{p}+1] = C_{\text{fol}}^{(t)}$	Eqn. (2) = Line 207
$\text{POOLS}[\text{p}+2] = C_{\text{roo}}^{(t)}$	Eqn. (3) = Line 208
